## **Exposing the Therapeutic Potential of Cannabigerolic Acid (CBGA); A Review**

**Presenter: Daniel Gana, Cannabis Researcher, Life Research Co.**

**Abstract:** Cannabigerolic acid (CBGA) is the first cannabinoid synthesized in Cannabis sativa L, hence the nickname “the mother of all cannabinoids”. It plays an important role in the biosynthesis of other cannabinoids. Although CBGA comes with ubiquitous therapeutic potential, the research thus far has focused primarily on its conversion to “neutral form” cannabinoids like CBD, CBG, and THC. This review paper aims to demonstrate the possible therapeutic potential of the “acid form” of the mother molecule, CBGA, from the available peer-reviewed literature. Our review focuses on the biosynthesis of CBGA, its bioactivity and therapeutic potential, and which central and peripheral nervous system cannabinoid targets are involved in its therapeutic activity.
